Summary:
The Bidirectionality of the marine reflectance, which derives from the anisotropy of the underwater light field, is an important parameter in ocean optics and ocean color remote sensing. A predictive model exists [1] for case 1 waters, whereas there is presently no model for optically-complex case 2 waters.

We present here the development of an underwater multi-spectral “radiance camera”. This instrument is characterized by a large-angle optic, a high-sensitivity CMOS and a compact design. The design of the camera is presented, and results from its characterization and from initial field experiments in the Mediterranean Sea are shown.

Anisotropy of the underwater light field:
The Bidirectionality of the marine reflectance can be expressed as the ratio between the upwelling irradiance ($E_u$) and the upwelling radiance ($L_u$) in a given direction:

$$Q(\lambda, \theta_s, \theta_v, \Delta\phi, \text{IOPs}) = \frac{E_u(\lambda, \theta_s, \text{IOPs})}{L_u(\lambda, \theta_v, \theta_s, \Delta\phi, \text{IOPs})}$$

$Q$ depends on:
- The sun position ($B_s$)
- The observation direction ($\theta_v, \Delta\phi$)
- Water optical properties (IOPs, in particular the Volume Scattering Function)

The radiance camera:

This development was funded by the French space agency (CNES). The design was proposed by the CIMEL company. The overall project is supervised by the Laboratoire d’Océanographie de Villefranche.

Characteristics:
- Radiation measurement on a full hemisphere (184° field of view).
- Measurements capability of upwelling or downwelling light field.
- Multispectral measurements (406, 438, 494, 510, 560 and 628 nm)
- Extremely compact design to reduce self-shading (Ø96 * 260 mm)
- High sensitive CMOS sensor, 12 bit digitization, HD format (1920 x 1080)
- Telecentric, non achromatic, patented fish-eye optics
- Auxiliary sensors: Compass, depth sensor, tilt sensor, Int. Temp. & humidity
- Deployment capability down to 100m depth

Preliminary field results:
The camera was tested in May 2008 during a cruise in the Mediterranean Sea (“Optic-Med”).

Acknowledgements:
The Centre National d’Etudes Spatiales (CNES) is acknowledged for the continuous support provided to this development. The Institut National des Sciences de l’Univers (INSU) is also thanked for the support provided for setting up the dark room where the characterization of the camera is performed. We express our gratitude to Frédéric Jourdin (SHOM) for the invitation to participate to the “Optic-Med” cruise, and to Bernard Gentili for his help in the computational aspects of the project.
